Typing Rules for PATINA

oyland, Junrui Liu

November 2, 2021

Notation:

- $\Gamma$  is the *type environment* that maps variables to their types.
- $\Delta$  stores the types of all global functions. It maps names of the functions to their argument and return types.
- Judgments of the form “ $\Delta; \Gamma \vdash e : T \dashv \Delta'; \Gamma'$ ” are *expression typing judgments*. It asserts that, under the environment pair  $\Delta; \Gamma$ , expression  $e$  has type  $T$ , and produces a new environment pair  $\Delta'; \Gamma'$ . Note that in PATINA,  $\Delta$  is not modified under expression typing, so it is always the case that  $\Delta' = \Delta$ .
  - When the environment  $\Gamma$  is also not modified, we use the abbreviation

$$\Delta; \Gamma \vdash e : T$$

in place of

$$\Delta, \Gamma \vdash e : T \dashv \Delta; \Gamma.$$

- Judgments of the form “ $\Delta \vdash_{\text{fn}} f(x : T) \rightarrow T_r, e$ ” are *function typing judgments*. It asserts that the function  $f$ , which takes in an argument  $x$  of type  $T$  and has body expression  $e$ , returns  $T_r$  under the global function environment  $\Delta$ . We only present the typing rules for single-argument functions, but they could be easily extended to account for multi-argument functions.
- Judgments of the form “ $\vdash_{\text{prog}} \text{fn}_1, \dots, \text{fn}_n$ ” are *program typing judgments*. It asserts that every function in the program is well-typed.

## 1 Expression Typing Rules (Basic)

The unit value has type Unit:

$$\frac{}{\Delta; \Gamma \vdash () : \text{Unit}} \text{T-UNIT}$$

Boolean constants have type Bool:

$$\frac{}{\Delta; \Gamma \vdash \text{true} : \text{Bool}} \text{T-TRUE}$$

$$\frac{}{\Delta; \Gamma \vdash \text{false} : \text{Bool}} \text{T-FALSE}$$

Integer constants have type Int:

$$\frac{i \in \mathbb{Z}}{\Delta; \Gamma \vdash i : \text{Int}} \text{T-INT}$$

The negation of a boolean expression has type Bool:

$$\frac{\Delta; \Gamma \vdash e : \text{Bool}}{\Delta; \Gamma \vdash !e : \text{Bool}} \text{T-NOT}$$

Binary arithmetic expressions have type Int:

$$\frac{\Delta; \Gamma \vdash e_1 : \text{Int} \quad \Delta; \Gamma \vdash e_2 : \text{Int} \quad \square \in \{+, -, *, /\}}{\Delta; \Gamma \vdash e_1 \square e_2 : \text{Int}} \text{T-ARITH}$$

Binary logical expressions have type Bool:

$$\frac{\Delta; \Gamma \vdash e_1 : \text{Bool} \quad \Delta; \Gamma \vdash e_2 : \text{Bool} \quad \square \in \{\&\&, \mid\mid\}}{\Delta; \Gamma \vdash e_1 \square e_2 : \text{Bool}} \text{T-LOGIC}$$

Integer comparisons have type Bool:

$$\frac{\Delta; \Gamma \vdash e_1 : \text{Int} \quad \Delta; \Gamma \vdash e_2 : \text{Int} \quad \square \in \{<, >, <=, >=\}}{\Delta; \Gamma \vdash e_1 \square e_2 : \text{Bool}} \text{T-COMPARE}$$

Two expressions of the same type can be checked for (in-)equality:

$$\frac{\Delta; \Gamma \vdash e_1 : T \quad \Delta; \Gamma \vdash e_2 : T \quad \square \in \{==, !=\}}{\Delta; \Gamma \vdash e_1 \square e_2 : \text{Bool}} \text{T-EQ}$$

An if expression has type T, if the condition is a boolean expression and the two branches both have type T:

$$\frac{\Delta; \Gamma \vdash e_1 : \text{Bool} \quad \Delta; \Gamma \vdash e_2 : T \quad \Delta; \Gamma \vdash e_3 : T}{\Delta; \Gamma \vdash \text{if } e_1 \text{ then } e_2 \text{ else } e_3 : T} \text{T-IF}$$

A while expression has type Unit, if the condition is a boolean expression and the body is a unit expression.

$$\frac{\Delta; \Gamma \vdash e_1 : \text{Bool} \quad \Delta; \Gamma \vdash e_2 : \text{Unit}}{\Delta; \Gamma \vdash \text{while } e_1 \text{ do } e_2 : \text{Unit}} \text{T-WHILE}$$

## 2 Expression Typing Rules (Advanced)

An variable  $x$  has type T under the type environment  $\Gamma$ , if looking up  $x$  in  $\Gamma$  yields T:

$$\frac{\Gamma(x) = T}{\Delta; \Gamma \vdash x : T} \text{T-VAR}$$

A let-expression assigns an expression  $e$  of type T to the variable  $x$ . The let-expression itself has type Unit, and it augments the type environment by mapping  $x$  to T:

$$\frac{\Delta; \Gamma \vdash e : T \dashv \Delta; \Gamma'}{\Delta; \Gamma \vdash \text{let } x : T = e : \text{Unit} \dashv \Delta; \Gamma[x \mapsto T]} \text{T-LET}$$

To type-check the sequence  $e_1; e_2$ , we check that the first expression has type Unit and the second expression has some type T. The type of the overall sequence is T.

$$\frac{\Delta; \Gamma_0 \vdash e_1 : \text{Unit} \dashv \Delta; \Gamma_1 \quad \Delta; \Gamma_1 \vdash e_2 : T \dashv \Delta; \Gamma_2}{\Delta; \Gamma_0 \vdash e_1; e_2 : T \dashv \Delta; \Gamma_2} \text{T-SEQ}$$

Note that this rule can be used to type-check arbitrarily long sequences. For example, to type check  $e_1; e_2; e_3$  (which should be read as “ $e_1; (e_2; e_3)$ ”), we first check  $e_1$ , and then  $(e_2; e_3)$ .

Remember that a sequence also delineates a scope. To type-check the scope, we check the expressions inside it, but in the end we restore the original environment.

程序代写代做CS编程辅导

$$\frac{\Delta; \Gamma \vdash \{e\} : \tau \quad \Delta; \Gamma' \vdash \tau}{\Delta; \Gamma \vdash \{e\} : \tau} \text{T-SCOPE}$$

If an variable  $x$  has type  $\tau$ , then we can assign an expression of the same type to  $x$ ; the assignment itself has type  $\text{Unit}$ .

$$\frac{\Delta; \Gamma \vdash e : \tau}{\Gamma \vdash x = e : \text{Unit}} \text{T-ASSIGN}$$

An integer array can be read or index:

$$\frac{\text{Arr} \quad \Delta; \Gamma \vdash e : \text{Int}}{\Delta; \Gamma \vdash x[e] : \text{Int}} \text{T-READ}$$

An element of an integer array can be overwritten with a new value.

$$\frac{\Gamma(x) = \text{Arr} \quad \Delta; \Gamma \vdash e_1 : \text{Int} \quad \Delta; \Gamma \vdash e_2 : \text{Int}}{\Delta; \Gamma \vdash x[e_1] = e_2 : \text{Unit}} \text{T-WRITE}$$

Assignment Project Exam Help

The result of calling a function of type  $\tau \rightarrow \tau_r$  with an argument of type  $\tau$  has type  $\tau_r$ :

$$\frac{\Delta(f) = \tau \rightarrow \tau_r \quad \Delta; \Gamma \vdash e : \tau}{\Delta; \Gamma \vdash f(e) : \tau_r} \text{T-CALL}$$

### 3 Function and Program Typing Rules

QQ: 749389476

To type-check a function definition against  $\Delta$  (containing types of all global function), we type-check the body of the function, where the initial type environment is just the parameters mapped to their declared types:

https://tutorcs.com

$$\frac{\Delta, x : \tau \vdash e : \tau_r}{\Delta \vdash_{\text{fn}} \text{fn } f(x : \tau) \rightarrow \tau_r \text{ } e} \text{T-FN}$$

To type-check a program, which is a list of function definitions, we populate  $\Delta$  with types of all global functions<sup>1</sup>, and then type-check each function against  $\Delta$ :

$$\frac{\begin{array}{l} \text{fn}_1 = \text{fn } f_1(x : \tau_1) \rightarrow \tau_{r_1} \text{ } e_1 \quad \dots \quad \text{fn}_n = \text{fn } f_n(x : \tau_n) \rightarrow \tau_{r_n} \text{ } e_n \\ \Delta \vdash_{\text{fn}} \text{fn } f_1(x : \tau_1) \rightarrow \tau_{r_1} \text{ } e_1 \quad \dots \quad \Delta \vdash_{\text{fn}} \text{fn } f_n(x : \tau_n) \rightarrow \tau_{r_n} \text{ } e_n \\ \Delta = f_1 : \tau_1 \rightarrow \tau_{r_1}; \dots; f_n : \tau_n \rightarrow \tau_{r_n} \end{array}}{\vdash_{\text{prog}} \text{fn}_1 \dots \text{fn}_n} \text{T-PROG}$$

<sup>1</sup>This enables us to type-check recursive functions.
